These waters, which were charged with copper derived from the weathering mass, percolated downward through the mineralized porphyry, and by chemical reaction with pyrite or with chalcopyrite deposited their copper, thus converting the previously subgrade material into ore (cementation enrichment). The most marked features of igneous metamorphism and mineralization along the mineralbearing zone, aside from the alteration of porphyry masses, are crystallization of limestone, bleaching of limestones and shales, formation of lime-bearing silicates and of jasperoid, and very general impregnation with pyrite. The total amount of introduced pyrite is very great, and this mineral is almost everywhere accompanied by minor amounts of chalcopyrite. Garnet, epidote, diopside, wollastonite, and tremolite are in places prominently developed. These silicates are invariably accompanied by metallic sulphides, mainly by pyrite, but in many places this mineral has chalcopyrite associated with it. In a few places zinc blende is also present. Galena is not characteristic of garnet-bearing phases of mineralization, though it does occur in a few places. Exploration has not developed any workable deposits of unoxidized copper ore adjacent to intrusive masses, and it seems probable that commercially important bodies of such ore do not exist. Enrichment of partly silicified pyrite limestone has produced ore carrying a maximum of 3 per cent copper adjacent to the mass of disseminated ore at Copper Flat and in the Old Glory mine, and additional ore masses of this nature may be discovered in other parts of the field. Certain...
